Reaction kinetics

## ABSTRACT

Ammonium bisulfate (ABS) is a viscous compound produced by the escape  $\text{NH}_3$  in the NO reduction process and  $\text{SO}_3$  in the flue gas at a certain temperature, which can cause the ash corrosion of the air preheater in coal-fired power plants. Therefore, it is essential to study the formation temperature of ABS to prevent the deposition of ABS in air preheaters. In this paper, the  $\text{SO}_3$  reaction kinetic model is used to analyze the  $\text{SO}_3$  generation process from coal combustion to the selective catalytic reduction (SCR) exit stage, and the kinetic model of NO reduction is used to analyze the  $\text{NH}_3$  escape process. A prediction model for calculating the ABS formation temperature based on the S content in coal and NO reduction parameters of the SCR is proposed, solving the difficulty of measuring  $\text{SO}_3$  concentration and  $\text{NH}_3$  concentration in the previous calculation equation of ABS formation temperature. And the reliability of the model is verified by the actual data of the power plant. Then the influence of S content in coal,  $\text{NH}_3/\text{NO}_x$  molar ratio, different  $\text{NO}_x$  concentrations at SCR inlet, and NO removal efficiency on the formation temperature of ABS are analyzed.

## 1. Introduction

The selective catalytic reduction (SCR) technology is widely used in the treatment of power plant tail gas due to its high efficiency of  $\text{NO}_x$  removal [1,2]. The escaped  $\text{NH}_3$  generated during the NO reduction process and the  $\text{SO}_3$  in the flue gas will generate ammonium bisulfate (ABS), which sticks to the air preheater, causing the pressure difference of the air preheater to rise.

Saleem *et al.* [3] and Burke *et al.* [4] conducted a theoretical analysis on the formation temperature of ABS and found that the formation temperature of ABS is related to the concentration of reactants  $\text{NH}_3$  and  $\text{SO}_3$ . Ammonium sulfate (AS) is the preferred product of thermodynamic analysis, and the resulting product is also affected by  $\text{NH}_3/\text{SO}_3$  molar ratio. Saleem *et al.* and Burke *et al.* predict the formation temperature of ABS is relatively low, between 150–190 °C and 180–215 °C respectively. Matsuda *et al.* [5] first carried out the experimental research on the formation temperature of ABS. And the reactant concentration in this experiment deviated from the actual power plant reactant concentration, and the ABS formation temperature obtained was higher, between 260 °C and 330 °C. Wei *et al.* [6] used acid dew point

measurement to measure the formation temperature of ABS. Menasha *et al.* [7] designed an experiment to simulate the formation of ABS with a single-channel air preheater and found that ABS was first appeared in the form of aerosol and then condensed on the wall. The formation temperatures of ABS predicted by Wei *et al.* and Menasha *et al.* are relatively close and are between those predicted by Saleem *et al.* and Matsuda *et al.* Although the formation temperature range of ABS obtained by different researchers is different under different experimental conditions, the formation temperature of ABS is positively correlated with the product of  $\text{NH}_3$  and  $\text{SO}_3$  concentrations.

According to many previous studies, the formation temperature of ABS is mainly measured by experimental methods, and it is mainly related to the concentration of escaped  $\text{NH}_3$  and the concentration of  $\text{SO}_3$  in the flue gas. Whether in the experiment or the actual operation of the power plant, it is difficult to accurately measure the concentration of escaped  $\text{NH}_3$  and  $\text{SO}_3$ , which makes it difficult to measure the formation temperature of ABS. To solve the thorny problem, a kinetic model of  $\text{SO}_3$  generated is built, which can get the concentration change of  $\text{SO}_3$  from the boiler to the SCR outlet according to the sulfur content in coal. Then the kinetic model of NO reduction is built, and the  $\text{NH}_3$  escape concentration can be obtained by some available parameters such as  $\text{NO}_x$  concentration at the inlet of the SCR and NO removal efficiency, etc. Finally, the experimental data

of Menasha *et al.*, which is the most precise experimental process of ABS formation temperature at home and abroad, is selected as an important basis, and the Clausius-Clapeyron relation is established to fit his experimental data to obtain the basic equation of ABS formation temperature, which is related to the concentration of  $\text{SO}_3$  and  $\text{NH}_3$ . Substituting the  $\text{SO}_3$  and  $\text{NH}_3$  in the equations with easily available coal sulfur content and parameters of NO reduction, respectively, a model can be obtained that predicts the formation temperature of ABS in flue gas by parameters such as coal sulfur content and parameters of NO reduction. This model cleverly solves the problem of the difficulty of measuring  $\text{SO}_3$  and  $\text{NH}_3$  to obtain the formation temperature of ABS, and the detailed flow chart is shown in Fig. 1.

## 2. Model Development

Firstly, based on the kinetic theory of S- $\text{SO}_2$ - $\text{SO}_3$  conversion, a model for obtaining the  $\text{SO}_3$  concentration in flue gas according to the sulfur content in coal is established. Then, based on the kinetic theory of NO reduction in the process of SCR, a model for calculating the  $\text{NH}_3$  escape concentration after SCR denitration is established based on the parameters of the NO reduction process. Finally, the established  $\text{SO}_3$  generation model and  $\text{NH}_3$  escape model are applied to the equation obtained by Menasha's experiment to explore the ABS formation temperature, and the prediction model of the formation temperature of ABS is obtained.

### 2.1. $\text{SO}_2$ produced by combustion of S in coal

There are more than 30 chemical elements in coal, and coal combustion is mainly a chemical reaction between combustible elements C, H and S in coal and oxygen in the air, and the flue gas produced mainly includes  $\text{N}_2$ ,  $\text{CO}_2$ ,  $\text{SO}_2$ , and water vapor. The  $\text{SO}_2$  concentration in the flue gas is related to the theoretical air supply, excess air coefficient, and theoretical flue gas volume. Assuming that the air required for fuel combustion and flue gas are ideal gases, the volume of  $\text{SO}_2$  produced by the combustion of 1 kg received base fuel is as shown in Eq. (1) and the  $\text{SO}_2$  concentration in the flue gas is as shown in Eq. (2) [8].

$$V_{\text{SO}_2} = 0.7 \times \frac{S_{\text{ar}}}{100} \quad (1)$$

$$C_{\text{SO}_2} = \frac{V_{\text{SO}_2}}{V_y} \quad (2)$$

where,  $V_{\text{SO}_2}$  represents the volume of  $\text{SO}_2$  produced by the combustion of 1 kg received base fuel,  $\text{m}^3 \cdot \text{kg}^{-1}$ ;  $S_{\text{ar}}$  represents the sulfur content in coal, kg;  $C_{\text{SO}_2}$  represents the  $\text{SO}_2$  concentration in the flue gas,  $\text{mg} \cdot \text{m}^{-3}$ ;  $V_y$  represents the actual amount of gas,  $\text{m}^3 \cdot \text{kg}^{-1}$ ; 0.7 represents 0.7  $\text{m}^3$   $\text{SO}_3$  produced by the complete combustion of 1 kg sulfur.

### 2.2. Generation model of $\text{SO}_3$

Almost all S contained in coal is converted into  $\text{SO}_2$  after combustion [9], and part of  $\text{SO}_2$  is converted into  $\text{SO}_3$  by homogeneous and heterogeneous reactions. The homogeneous reaction is mainly the gas phase reaction in the furnace flame combustion, and the heterogeneous reaction is mainly the gas-solid catalytic reaction of fly ash and the SCR catalyst in the flue gas. The chemical reactions involved in the model are included in R(1) – R(4) [10].

#### 2.2.1. Homogeneous formation of $\text{SO}_3$

Some scholars have analyzed the elementary reactions in the process of  $\text{SO}_3$  homogeneous reaction under boiler combustion conditions by CHEMIKIN software, and the main reactions involved are R(1) – R(3) [11]. The  $\text{H}_2\text{O}$  and  $\text{O}_2$  in the flue gas will increase the amount of OH and O and promote the formation of  $\text{SO}_3$ . The detailed elementary reactions involved are more complicated and difficult to use and calculate. To simplify the calculation process of homogeneous and heterogeneous reaction of  $\text{SO}_3$ , the oxidation process of  $\text{SO}_2$  is simplified as R(4). The research of Graham *et al.* [12] found that the reaction order of  $\text{SO}_2$  in the R(4) is 1, and the reaction order of  $\text{O}_2$  is 0.5. Therefore, the reaction rate Eqs. (3) and (4) of  $\text{SO}_3$  formation can be obtained based on the kinetics of the chemical reaction and the conversion rate of  $\text{SO}_3$  in the process of  $\text{SO}_2$  oxidation in the furnace is shown in Eq. (5).

$$R_{f1} = K_1 \times C_{\text{SO}_2} \times C_{\text{O}_2}^{0.5} \quad (3)$$

$$K_1 = A_1 \times \exp(-E_{a1}/RT) \quad (4)$$

$$\eta = \frac{C_{\text{SO}_3}}{C_{\text{SO}_2}} \times 100\% \quad (5)$$

where,  $A_1$  represents the pre-exponential factor,  $(\text{m}^3 \cdot \text{mg}^{-1})^{0.5} \cdot \text{s}^{-1}$ ;  $E_{a1}$  represents the activation energy,  $\text{kJ} \cdot \text{mol}^{-1}$ ;  $R$  represents the gas constant,  $8.3145 \text{ J} \cdot \text{mol}^{-1} \cdot \text{K}^{-1}$ ;  $T$  represents the absolute temperature, K;  $C_{\text{SO}_2}$  and  $C_{\text{O}_2}$  represent the mass concentration of  $\text{SO}_2$  and  $\text{O}_2$ ,  $\text{mg} \cdot \text{m}^{-3}$ ;  $C_{\text{SO}_3}$  represent the mass concentration of  $\text{SO}_3$ ,  $\text{mg} \cdot \text{m}^{-3}$ .

Studies [13,14] show that the homogeneous oxidation rate of  $\text{SO}_2$  decreases when the temperature is lower than 900 °C. Liu and Fleig *et al.* [15,16] studied the relationship between  $\text{SO}_3$  conversion rate and temperature and found that the reaction rate increased with the increase of temperature when the temperature was between 800 and 1100 °C, and decreased when the temperature was higher than 1100 °C. This is because R(2) and R(3) play a major role in the formation of  $\text{SO}_3$  at 800 °C – 1100 °C. With the increase of temperature, the OH content produced by the decomposition of  $\text{H}_2\text{O}$  increases, which promotes the positive reaction of R(2), and then promotes the formation of  $\text{SO}_3$  in R(3). When the temperature is higher than 1100 °C, the main effect on the formation of  $\text{SO}_3$  is R(1). When the temperature is higher, the decomposition of  $\text{HOSO}_2$  occurs, reducing the  $\text{SO}_3$  generated in R(2) and R(3), and the decomposition reaction of  $\text{SO}_3$  is accelerated.

#### 2.2.2. Formation of $\text{SO}_3$ catalyzed by fly ash

The flue gas fly ash contains  $\text{SiO}_2$ ,  $\text{Al}_2\text{O}_3$ ,  $\text{Fe}_2\text{O}_3$ , and other compounds, which have a certain catalytic effect on the  $\text{SO}_2$  contained in the flue gas and  $\text{Fe}_2\text{O}_3$  has a more obvious catalytic effect on  $\text{SO}_2$ . Kim *et al.* [17] studied the catalytic reaction mechanism of fly ash and found that the reaction order of  $\text{SO}_2$  is 1, and the reaction order of  $\text{O}_2$  is 0.5. The reaction rate equation of  $\text{SO}_2$  catalytic oxidation is proposed as follows:

$$R_{f2} = K_2 \times C_{\text{SO}_2} \times C_{\text{O}_2}^{0.5} \quad (6)$$

$$K_2 = A_2 \times \exp(-E_{a2}/RT) \quad (7)$$

Xiao *et al.* [18] studied the fly ash formed at different furnace temperatures and found that the fly ash in the high temperature furnace (above 1500 °C) contains complex iron oxides with more oxygen vacancies, which has a more obvious catalytic effect on  $\text{SO}_2$  than  $\text{Fe}_2\text{O}_3$ . The catalytic effect of fly ash containing composite

Fig. 1. Flow chart of the ABS formation temperature model.

iron oxide on  $\text{SO}_2$  first increases and then decreases with the increase of temperature and the catalytic effect is most obvious at  $900^\circ\text{C}$ , which may be related to the participation of other substances such as  $\text{CaO}$  contained in fly ash in chemical reactions. Therefore, the reaction rate constant  $K_2$  in Eq. (6) needs to be discussed in different temperature ranges.

### 2.2.3. Formation of $\text{SO}_3$ catalyzed by catalyst during NO reduction

In the SCR process,  $\text{V}_2\text{O}_5\text{-WO}_3/\text{TiO}_2$  is the most commonly used catalyst, containing Ti, W, V, and other elements, among which  $\text{V}_2\text{O}_5$  has the most significant catalytic effect on  $\text{SO}_2$ . Svachula *et al.* [19] systematically studied the effects of experimental operating conditions, catalyst design parameters, and gas composition ( $\text{O}_2$ ,  $\text{SO}_2$ ,  $\text{H}_2\text{O}$ ,  $\text{NO}_x$  and  $\text{NH}_3$  concentration) on the catalytic oxidation of  $\text{SO}_2$  to  $\text{SO}_3$  on honeycomb commercial catalysts. Combined with the catalytic reaction mechanism of  $\text{SO}_2$ , a kinetic model of  $\text{SO}_2$  catalytic oxidation reaction is proposed [20]:

$$R_{f,2} = \frac{k_1 \cdot C_{\text{SO}_2} \cdot C_{\text{SO}_3} \cdot (1 + b \cdot C_{\text{NO}})}{1 + k_2 \cdot C_{\text{SO}_3} + k_3 \cdot C_{\text{SO}_2} \cdot C_{\text{SO}_3} + k_4 \cdot C_{\text{SO}_3} \cdot C_{\text{H}_2\text{O}} + k_5 \cdot C_{\text{NH}_3} \cdot C_{\text{SO}_3} + k_6 \cdot C_{\text{SO}_2} \cdot \frac{C_{\text{SO}_2}}{\sqrt{C_{\text{O}_2}}}} \quad (8)$$

where,  $C_{\text{SO}_2}$ ,  $C_{\text{SO}_3}$ ,  $C_{\text{NO}}$ ,  $C_{\text{H}_2\text{O}}$ ,  $C_{\text{NH}_3}$ ,  $C_{\text{O}_2}$  respectively represent the molar concentration of  $\text{SO}_2$ ,  $\text{SO}_3$ ,  $\text{NO}$ ,  $\text{H}_2\text{O}$ ,  $\text{NH}_3$ ,  $\text{O}_2$  in the flue gas,  $\text{mol}\cdot\text{cm}^{-3}$ ;  $k_1, k_2, k_3, k_4, k_5, k_6$  and  $b$  respectively represent the influence coefficients of different substances.

The kinetic equation can explain the following phenomena in related experimental studies [20]: When the  $\text{SO}_2$  concentration is low, the  $\text{SO}_2$  reaction order is about 1, but with the increase of  $\text{SO}_2$  concentration, the reaction order of  $\text{SO}_2$  decreases; When the concentration of  $\text{O}_2$  is high, the effect on the catalytic reaction of  $\text{SO}_2$  is almost zero;  $\text{H}_2\text{O}$  and  $\text{NH}_3$  have a certain promotion effect;  $\text{NO}$  has a certain promotion effect on the catalytic oxidation of  $\text{SO}_2$ .

### 2.3. $\text{NH}_3$ escape model

$\text{NH}_3$  is one of the important reactants of ABS. Based on SCR reaction kinetics, this section combines SCR reactor performance index reactor potential, the generation of escaped  $\text{NH}_3$  is explored [21,22]. Relevant studies [23] have shown that the E-R mechanism

is suitable for reactions above  $200^\circ\text{C}$ , and the L-H mechanism is suitable for reactions below  $200^\circ\text{C}$ . The temperature range of NO reduction is generally  $300\text{--}400^\circ\text{C}$  in the SCR, so the E-R mechanism is dominant. Therefore, the reaction kinetics of NO reduction is built based on the E-R mechanism [24,25], such as Eqs. (9)–(11). Combined with the reaction rate of NO reduction and the time of flue gas passes through the SCR catalyst, the  $\text{NO}_x$  concentration at the outlet of the SCR and its removal efficiency can be obtained as Eq. (12).

$$R_{\text{NO}} = K_3 \times C_{\text{NO}} \times \frac{aC_{\text{NH}_3}}{1 + aC_{\text{NH}_3}} \quad (9)$$

$$K_3 = A_3 \times \exp(-E_1/RT) \quad (10)$$

$$a = a_0 \times \exp(-E_2/RT) \quad (11)$$

$$\eta = \frac{C_{\text{NO}_x\text{in}} - C_{\text{NO}_x\text{out}}}{C_{\text{NO}_x\text{in}}} \times 100\% \quad (12)$$

where,  $R_{\text{NO}}$  represents the reaction rate of NO,  $\text{mol}\cdot\text{m}^{-3}\cdot\text{s}^{-1}$ ;  $C_{\text{NO}}$  and  $C_{\text{NH}_3}$  represent the molar concentration of NO and  $\text{NH}_3$ ,  $\text{mol}\cdot\text{m}^{-3}$ ;  $a$  represents the adsorption rate constant of  $\text{NH}_3$ ,  $\text{s}^{-1}$ ;  $\eta$  represents the NO removal efficiency, %;  $C_{\text{NO}_x\text{in}}$  and  $C_{\text{NO}_x\text{out}}$  respectively represent the NO inlet and outlet concentration of the SCR reactor,  $\text{mg}\cdot\text{m}^{-3}$ .

After conducting a large number of experiments and field tests, Song *et al.* proposed the potential  $P$  of the SCR reactor to measure the performance of the SCR catalyst under actual flue gas conditions [21]. The relationship between reactor potential and NO removal efficiency,  $\text{NO}_x$  concentration,  $\text{NH}_3/\text{NO}_x$  molar ratio, and  $\text{NH}_3$  escape concentration is as follows Eqs. (13) and (14). The Eq. (15) of  $\text{NH}_3$  escape concentration can be obtained by combining Eqs. (9)–(14).

$$P = 0.5 \times \ln\left[\frac{M_R}{(M_R - \eta) \times (1 - \eta)}\right] \quad (13)$$

$$M_R = \frac{\eta}{100} + 2.7 \times \frac{C_{\text{NH}_3}}{C_{\text{NO}_x\text{in}}} \quad (14)$$

$$C_{\text{NH}_3} = \frac{\eta}{(1 - \eta) \times \exp(2 \times P) - 1} \times \frac{C_{\text{NO}_x \text{in}}}{1.765} \quad (15)$$

where,  $P$  represents the potential of the reactor;  $M_R$  represents the molar ratio of  $\text{NH}_3/\text{NO}_x$ ;  $\eta$  represents the NO removal efficiency;  $C_{\text{NH}_3}$  represents the concentration of escape  $\text{NH}_3$ ,  $\text{mg} \cdot \text{m}^{-3}$ ;  $C_{\text{NO}_x \text{in}}$  represents the  $\text{NO}_x$  concentration at the SCR inlet,  $\text{mg} \cdot \text{m}^{-3}$ .

#### 2.4. Prediction model of ABS formation temperature

Comparing with several existing experiments about ABS formation temperature, it is found that Menasha *et al.*'s experimental process is more precise and the physical model was established to simulate the single-channel air preheater to study the formation temperature of ABS. The advantages of this experiment are outstanding, and the measurement accuracy is extremely high and its innovation of this experiment lies in not only the visual observation and electrode measurement of generation of ABS, but also the design of a control experiment without thermocouple and electrode interference to avoid the influence of thermocouple and electrode, which is not found in other studies about formation temperature of ABS. In addition, the  $\text{NH}_3$  and  $\text{SO}_3$  concentrations of the typical SCR outlet selected in this experiment are also more in line with the actual process, and the actual operating conditions of the air preheater are simulated as accurately as possible in every detail. The experimental data show that the formation temperature of ABS is related to the concentration of reactants. The higher the concentration product of reactants, the higher the formation temperature of ABS. There is two equilibrium in the reaction process of ABS formation: the first is the chemical reaction equilibrium in which  $\text{NH}_3$  reacts with  $\text{SO}_3$  (or  $\text{H}_2\text{SO}_4$ ) to form gas phase ABS, and the second is the condensation equilibrium in which gas phase ABS condenses into liquid ABS when it is cold, as follows R(5):

The relationship between temperature and pressure in the process of ABS condensation equilibrium can be expressed by the Clausius–Clapeyron relation. Due to technical reasons, it is difficult to measure the partial pressure of ABS. Because the concentration of the reactant is related to the partial pressure of the reactant, the concentration product of  $\text{NH}_3$  and  $\text{SO}_3$  is used to represent the partial pressure of ABS. Therefore, the concentration of ABS can be expressed as the relationship between the  $\text{NH}_3$  and  $\text{SO}_3$  concentration product and the temperature, as shown in Fig. 2.

According to the Clausius–Clapeyron relation, the relationship between  $\text{NH}_3$  concentration,  $\text{SO}_3$  concentration, and the formation temperature of ABS is obtained as Eq. (16). Combined with Eqs. (3), (6), (8), (15), and (16), the prediction model of ABS formation temperature is obtained as Eqs. (17)–(19).

$$[\text{NH}_3] \cdot [\text{SO}_3] = 7.962 \times 10^{12} \times \exp(-190319/RT) \quad (16)$$

$$T_{\text{IFT}} = \frac{22.89}{20.804 - \ln(C_{\text{NH}_3} \cdot C_{\text{SO}_3}/10^{12})} \times 1000 - 273.15 \quad (17)$$

$$C_{\text{NH}_3} = \frac{\eta}{(1 - \eta) \times \exp(2 \times P) - 1} \times \frac{C_{\text{NO}_x \text{in}}}{1.765} \quad (18)$$

$$C_{\text{SO}_3} = C_{\text{SO}_3 \text{f1}} + C_{\text{SO}_3 \text{f2}} + C_{\text{SO}_3 \text{f3}} \quad (19)$$

where,  $[\text{NH}_3] \cdot [\text{SO}_3]$  represents the concentration product of  $\text{NH}_3$  and  $\text{SO}_3$ ,  $\text{mg}^2 \cdot \text{m}^{-6}$ ;  $R$  represents gas constant;  $T$  represents ABS formation temperature, K;  $T_{\text{IFT}}$  represents the ABS formation temperature, °C;  $C_{\text{NH}_3}$  represents the escape concentration of  $\text{NH}_3$ ,  $\text{mg} \cdot \text{m}^{-3}$ ;

$C_{\text{SO}_3}$  represents the  $\text{SO}_3$  concentration at the inlet of the air preheater,  $\text{mg} \cdot \text{m}^{-3}$ ;  $C_{\text{SO}_3 \text{f1}}$ ,  $C_{\text{SO}_3 \text{f2}}$  and  $C_{\text{SO}_3 \text{f3}}$  represent  $\text{SO}_3$  produced by the homogeneous reaction,  $\text{SO}_3$  produced by fly ash catalysis, and  $\text{SO}_3$  produced by SCR catalyst respectively,  $\text{mg} \cdot \text{m}^{-3}$ .

### 3. Results and Discussion

The prediction model of ABS formation temperature established in Section 2 is based on the coupling of the  $\text{SO}_3$  prediction model and the  $\text{NH}_3$  escape model. Subsequently, the  $\text{SO}_3$  model and  $\text{NH}_3$  escape model are verified by the actual measurement data of the power plant, and then the correctness of the formation temperature prediction model of ABS is indirectly verified. Then, the effects of S content,  $\text{NH}_3/\text{NO}_x$  molar ratio,  $\text{NO}_x$  concentration at different SCR inlet, and different NO removal efficiency on the formation temperature of ABS are analyzed.

#### 3.1. Model validation

To verify the correctness of the  $\text{SO}_3$  prediction model and the  $\text{NH}_3$  escape model built in this paper, firstly, the test data of more than 40 units of the power plant are used to analyze, and the results show that the potential of the reactor decreases with the increase of operation time of units, but the degradation trend slows down as shown in Fig. 3. The reactor potential degradation Eq. (20) is obtained by fitting its data. The potential of the reactor increases with the decrease of unit operating load rate, as shown in Fig. 4. Based on the field test data, the relationship between the potential  $P_0$  of the reactor and the operating load rate of the unit is as shown in Eq. (21).

$$\frac{P}{P_0} = \exp\left(-\frac{t}{118000}\right) \quad (20)$$

$$P_0 = -0.534 \times L + 3.67 \quad (21)$$

where,  $t$  represents the cumulative operating time, h;  $P_0$  represents the reactor potential at a fixed unit operating load rate;  $L$  represents unit operating load rate, %.

Under the quality parameters of as-received coal as shown in Table 1, the amount of  $\text{SO}_3$  generated by the homogeneous reaction of  $\text{SO}_2$ , fly ash catalysis, and the catalytic oxidation of  $\text{V}_2\text{O}_5$  in the SCR catalyst is calculated, and the parameters used in the model calculation are shown in Table 2 and Table 3. The amount of  $\text{SO}_3$

Fig. 2. Experimental data fitting of Menasha *et al.* [7].

Fig. 3. Derioration trend of reactor potential over time.

Fig. 4. The relationship between reactor potential and load rate.

generated in the three ways as shown in Fig. 5. Among them, the amount of  $\text{SO}_3$  generated by the catalytic oxidation of  $\text{V}_2\text{O}_5$  is the largest, which is  $56.46 \text{ mg}\cdot\text{m}^{-3}$ ; the second is generated by the homogeneous phase, which is  $31.9 \text{ mg}\cdot\text{m}^{-3}$ ; the amount of  $\text{SO}_3$  generated by fly ash is the least, which is  $6.1 \text{ mg}\cdot\text{m}^{-3}$ , of which the proportion of  $\text{SO}_3$  generated by the SCR catalyst accounts for the largest, which is 60%. Therefore, reducing catalytic rate of the  $\text{SO}_2$  in the SCR catalyst is the key to reducing the  $\text{SO}_3$  in the flue gas.

It can be seen from Fig. 6 that the value predicted of  $\text{SO}_3$  and the mean value measured at the SCR inlet of the power plant are  $38 \text{ mg}\cdot\text{m}^{-3}$  and  $36.36 \text{ mg}\cdot\text{m}^{-3}$ , respectively, with a relative error of 4.32%. the value predicted of  $\text{SO}_3$  and the mean value measured at the exit of SCR are  $94.46 \text{ mg}\cdot\text{m}^{-3}$  and  $83.34 \text{ mg}\cdot\text{m}^{-3}$ , respectively, with a relative error of 11.77%. The predicted value of  $\text{NH}_3$  escape is  $2.15 \text{ mg}\cdot\text{m}^{-3}$ , the actual measured average value is  $2.39 \text{ mg}\cdot\text{m}^{-3}$ , and the relative error is 10.04%. The predicted value of  $\text{SO}_3$  is consistent with the actual value at the SCR inlet, the deviation of  $\text{SO}_3$  concentration is slightly larger at the SCR outlet, and the predicted value of  $\text{SO}_3$  concentration is in good agreement with the actual value as a whole. Similarly, the prediction model of  $\text{NH}_3$  escape is more accurate, as shown in Fig. 7. The model has high accuracy and good universality and the prediction errors of  $\text{SO}_3$  and  $\text{NH}_3$

are within the acceptable range The ABS prediction model is a coupling of the  $\text{SO}_3$  generation model and the  $\text{NH}_3$  escape model, which indirectly proves the accuracy of the ABS prediction model.

### 3.2. The effect of S in coal on the formation temperature of ABS

Fig. 8 shows the effect of different sulfur content in coal on the formation temperature of ABS. As the S content in coal increases, the  $\text{SO}_3$  content in the flue gas increases almost linearly, while the escaped  $\text{NH}_3$  volume hardly changes, and the formation temperature of ABS increases, but the growth rate slows down. When the concentration of  $\text{NH}_3$  in flue gas is  $3.9 \text{ mg}\cdot\text{m}^{-3}$  and the content of S in the coal changes from 0.1% to 3%, the formation temperature of ABS increases from  $209^\circ\text{C}$  to  $243.6^\circ\text{C}$ , which increases by  $34.6^\circ\text{C}$ . Especially when the S content is within 1%, the formation temperature of ABS increases rapidly with the increase of S content.

With the increase of sulfur content in coal, the concentration product of  $\text{SO}_3$  and  $\text{NH}_3$  increases, which makes the formation temperature of ABS increase. To reduce the ABS formation temperature, the power plant burns low-sulfur coal as much as possible so that ABS is deposited as much as possible on the cold end of the air preheater instead of the middle section, so that the air preheater can use soot blowing and hot air circulation to reduce the deposited ABS. When the S content in the coal exceeds 2%, the temperature of ABS formation changes little with the increase of the content of S in the coal.

### 3.3. Effect of $\text{NH}_3/\text{NO}_x$ molar ratio on the temperature of ABS formation

To study the influence of  $\text{NH}_3/\text{NO}_x$  single factor on ABS formation temperature, NO reduction efficiency is fixed at 90%. Fig. 9 shows the effect of different  $\text{NH}_3/\text{NO}_x$  molar ratios on the formation temperature of ABS. It can be seen from Fig. 9 that with the increase of  $\text{NH}_3/\text{NO}_x$  molar ratio from 0.7 to 1.2, the concentration of escaped  $\text{NH}_3$  increased from  $3.18 \text{ mg}\cdot\text{m}^{-3}$  to  $4.79 \text{ mg}\cdot\text{m}^{-3}$ , with an increase of 50.6%. While the concentration of  $\text{SO}_3$  gradually decreased from  $85.29 \text{ mg}\cdot\text{m}^{-3}$  to  $64.06 \text{ mg}\cdot\text{m}^{-3}$ , with a decrease of 24.9%; and the formation temperature of ABS changed little, only increased by  $1.4^\circ\text{C}$ . The concentration of  $\text{NH}_3$  in the flue gas increases but  $\text{SO}_3$  decreases and the concentration product of  $\text{NH}_3$  and  $\text{SO}_3$  has little change, so the formation temperature of ABS has little change.

The increase of  $\text{NH}_3/\text{NO}_x$  molar ratio will seriously increase the concentration of escape  $\text{NH}_3$ . The main reason is that the ideal ratio of  $\text{NH}_3$  to NO reaction is 1:1. When  $\text{NH}_3/\text{NO}_x$  is excessively increased, the amount of  $\text{NH}_3$  that is not involved in the reaction in the flue gas is increased severely, resulting in serious  $\text{NH}_3$  escaping. On the contrary, the  $\text{SO}_3$  concentration in the flue gas decreases, because the escape  $\text{NH}_3$  increased with the increase of  $\text{NH}_3/\text{NO}_x$  during NO reduction, which inhibits the conversion of  $\text{SO}_2$  to  $\text{SO}_3$ , thereby reducing the concentration of  $\text{SO}_3$ , which is consistent with the results of Svachula *et al* [19]. In the actual process, adding ammonia injection grids and baffles in the SCR flue to reduce the unevenness of the local  $\text{NH}_3/\text{NO}_x$  molar ratio can reduce the escape of  $\text{NH}_3$ , thereby reducing the formation temperature of ABS.

### 3.4. The effect of different $\text{NO}_x$ inlet concentrations on the formation temperature of ABS

It can be seen from Fig. 10 that with the increase of the  $\text{NO}_x$  concentration at the SCR inlet the ABS formation temperature gradually increases, which is consistent with the research results of Si *et al* [26]. The main reason is that when the rate of  $\text{NH}_3/\text{NO}_x$  is fixed at 0.908, the concentration of escape  $\text{NH}_3$  increases with the increase of  $\text{NO}_x$  concentration at the SCR inlet, thereby reducing the  $\text{SO}_3$  concentration. Generally speaking, the formation tempera-

ture of ABS increases with the increase of the concentration product of NH<sub>3</sub> and SO<sub>3</sub>. With the increase of the NO<sub>x</sub> concentration at the SCR inlet, the NO removal efficiency decreases, resulting in an increase of the amount of escaped NH<sub>3</sub>; The reason for the decrease of SO<sub>3</sub> concentration may be that excessive NH<sub>3</sub> occupies more V<sup>5+</sup> vacancies, which inhibits the oxidation process of SO<sub>2</sub> on V<sub>2</sub>O<sub>5</sub>.

Therefore, the rational use of technologies such as low-nitrogen combustion in power plants not only reduces the concentration of

NO<sub>x</sub> emissions but also helps reduce the formation temperature of ABS, thereby reducing the condensation of ABS in the middle temperature section of the air preheater.

### 3.5. The effect of NO removal efficiency on ABS formation temperature

To study the effect of NO removal efficiency on the formation temperature of ABS, the molar ratio of NH<sub>3</sub>/NO<sub>x</sub> is fixed as 1. The influence of different NO removal efficiency on the formation temperature of ABS can be seen in Fig. 11. With the increase of no removal efficiency, the formation temperature of ABS increases gradually, and the growth rate increases, while the SO<sub>3</sub> concentration in the flue gas hardly changes, but the concentration of NH<sub>3</sub> escape increases gradually. Especially when the NO removal efficiency exceeds 90%, if the NO removal efficiency continues to increase, the concentration of NH<sub>3</sub> escape will increase rapidly, and the formation temperature of ABS will increase rapidly, which causes ABS to be produced at a higher temperature, causing more serious clogging and corrosion problems to the SCR catalyst and air preheater.

The interaction between NH<sub>3</sub>/NO<sub>x</sub> molar ratio and NO removal efficiency can be seen in Fig. 12. With the increase of NH<sub>3</sub>/NO<sub>x</sub> molar ratio, the NO removal efficiency increases rapidly at first, but when the NH<sub>3</sub>/NO<sub>x</sub> molar ratio exceeds 0.9, the NO removal efficiency increases very little with the increase of NH<sub>3</sub>/NO<sub>x</sub> molar ratio, but the concentration of escape NH<sub>3</sub> increases very fast. The synergistic effect between NH<sub>3</sub>/NO<sub>x</sub> molar ratio and no removal efficiency on ABS formation temperature is shown in Fig. 13. When NH<sub>3</sub>/NO<sub>x</sub> molar ratio exceeds 0.9, if the NH<sub>3</sub>/NO<sub>x</sub> molar ratio continues to increase, the ABS formation temperature will increase rapidly. The comprehensive effect between NH<sub>3</sub>/NO<sub>x</sub> molar ratio and NO removal efficiency on the formation temperature of ABS is shown in Fig. 13. When NH<sub>3</sub>/NO<sub>x</sub> molar ratio exceeds 0.9, if the NH<sub>3</sub>/NO<sub>x</sub> molar ratio continues to increase, the formation temperature of ABS will increase rapidly. Therefore, to reduce the formation temperature of ABS, it is necessary to rationally balance the relationship between the NH<sub>3</sub>/NO<sub>x</sub> molar ratio and the NO removal efficiency, and try to control the NH<sub>3</sub>/NO<sub>x</sub> molar ratio at about 0.9, which can ensure the higher NO removal efficiency at 85%–90%, and control the lower concentration of escaped NH<sub>3</sub>.

## 4. Conclusions

In this study, a prediction model of ABS formation temperature in air preheater of the coal-fired power plant was established by

combining the reaction kinetics of  $\text{SO}_3$  and kinetics of NO reduction. The amount of  $\text{SO}_3$  generated from the combustion of S in coal to the inlet of the air preheater was calculated by the reaction kinetics of  $\text{SO}_3$ , and the concentration of escaped  $\text{NH}_3$  was calculated by the reaction kinetics of NO reduction, and finally, the model of predicting the ABS formation temperature was obtained. Considering the whole process, the prediction model of ABS formation temperature obtained by using S content in coal and parameters of NO reduction overcomes the difficulty of calculating the formation temperature of ABS by measuring the  $\text{SO}_3$  concentration and  $\text{NH}_3$  concentration in the past, and the prediction results of the model are in good agreement with the actual data, which has good applicability.

The following conclusions can be noted:

(1) The prediction model of  $\text{SO}_3$  concentration shows that in the process of coal combustion to the SCR outlet, the  $\text{SO}_3$  generated by the catalysis of  $\text{V}_2\text{O}_5$  accounted for 60%, by the homogeneously generated  $\text{SO}_3$  accounted for 33.8%, and the fly ash catalyzed  $\text{SO}_3$  accounted for 6.2%. Reducing the catalytic oxidation of  $\text{SO}_2$  on the SCR catalyst is the key to reducing the concentration of  $\text{SO}_3$ , which is beneficial to lower the formation temperature of ABS, thereby slowing down the deposition of ABS on the air preheater.

(2) The formation temperature of ABS is directly related to the S content in coal. The increase of the sulfur content in coal leads to the increase of  $\text{SO}_3$  concentration in the flue gas, which makes the formation temperature of ABS increase rapidly. To reduce the influence of ABS from the source, low sulfur coal should be burned as far as possible or desulfurization treatment should be carried out before combustion.

(3) Although the change of the  $\text{NH}_3/\text{NO}_x$  molar ratio has little effect on the ABS formation temperature when the  $\text{NH}_3/\text{NO}_x$  deviates from the design value seriously, it will cause serious  $\text{NH}_3$  escape. Therefore, in practical, adding ammonia injection grid and guide plate in SCR Flue can reduce the non-uniformity of local  $\text{NH}_3/\text{NO}_x$  molar ratio, which can not only improve the NO removal efficiency but also effectively reduce  $\text{NH}_3$  escape, thus reducing the

formation temperature of ABS. When the  $\text{NH}_3/\text{NO}_x$  molar ratio is fixed, the formation temperature of ABS increases with the increase of the emission concentration of  $\text{NO}_x$  at the SCR inlet. Therefore, the use of low-nitrogen combustion technology not only reduces  $\text{NO}_x$  emissions concentration, but also reduces the formation temperature of ABS.

(4) Although the improvement of NO removal efficiency has little effect on the  $\text{SO}_3$  concentration, it has a greater impact on the concentration of  $\text{NH}_3$  escape. As the NO removal efficiency exceeds 90%, continuing to increase the  $\text{NH}_3/\text{NO}_x$  molar ratio will not significantly improve the NO removal efficiency, but will increase the  $\text{NH}_3$  concentration rapidly, resulting in the rapid increase of ABS formation temperature. Therefore, to control the formation temperature of ABS, adjusting the  $\text{NH}_3/\text{NO}_x$  molar ratio at about 0.9 can not only ensure the NO removal efficiency at 85%–90% but also control the concentration of  $\text{NH}_3$  escape at a low level.

| $R_{f, 3}$             | De- $NO_x$ catalytic $SO_3$ generation rate, $\text{mol}\cdot\text{L}^{-1}\cdot\text{s}^{-1}$ |
| $R_{NO}$               | the reaction rate of $NO$ , $\text{mol}\cdot\text{m}^{-3}\cdot\text{s}^{-1}$                  |
| $S$                    | sulphur content in coal, %                                                                    |
| $S_{ar}$               | the sulfur content in coal, kg                                                                |
| $[SO_3]$               | $SO_3$ concentration, $\text{mg}\cdot\text{m}^{-3}$                                           |
| $T$                    | the absolute temperature, K                                                                   |
| $T_{IFT}$              | the ABS formation temperature, $^{\circ}\text{C}$                                             |
| $V_{SO_2}$             | the volume of $SO_2$ , $\text{m}^3\cdot\text{kg}^{-1}$                                        |
| $V_y$                  | the actual amount of gas, $\text{m}^3\cdot\text{kg}^{-1}$                                     |
| $\eta$                 | $NO$ removal efficiency, %                                                                    |

## Subscript

|     |                            |
|-----|----------------------------|
| ar  | as-received basis          |
| in  | the $NO$ at the SCR inlet  |
| out | the $NO$ at the SCR outlet |
